

# Data Structure and Algorithms

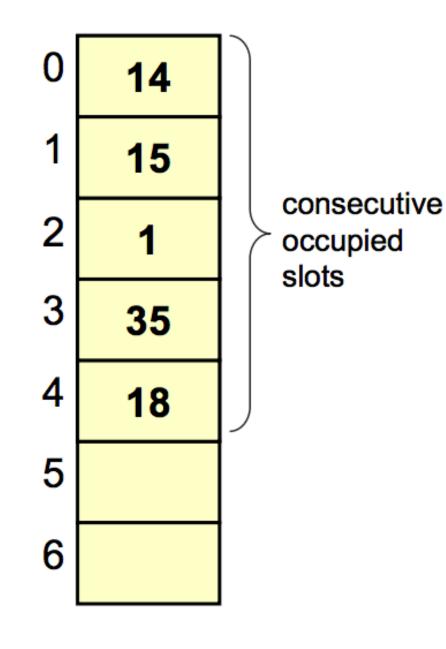

Session-32

Dr. Subhra Rani Patra SCOPE, VIT Chennai

#### **Clustering Problem**

- As long as table is big enough, a free cell can always be found, but the time to do so can get quite large.
- Worse, even if the table is relatively empty, blocks of occupied cells start forming.
- This effect is known as primary clustering.
- Any key that hashes into the cluster will require several attempts to resolve the collision, and then it will add to the cluster.

- A cluster is a collection of consecutive occupied slots
- A cluster that covers the home address of a key is called the primary cluster of the key
- Linear probing can create large primary clusters that will increase the running time of find/insert/delete operations

#### **Extendible Hashing**

- Hardle large arount of data.
- The data to be placed in the hart table is by extracting certain no of bits.

- The bucket can hold the data of its global depth.

- Et data in bucket is more than global depth, then split the bucket and double the directory

each page can hold 2 date entries (2 is the depth).

of ep I: 97 seaf 1, y

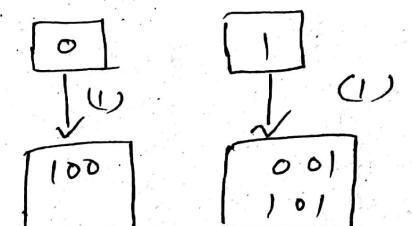

1 = 001 4 = 100 > 975ert 5

Bucket is full. Here double the directory

1 = 001

4=100

5 = 101

we will examine last bit of data and issest the data in bucket.

II: Insert 7 Bucket is full. Here double the directory and split the bucket After insertion of 7, consider last two bits.

Step 3: 90 sept 8

$$8 = 1000$$

#### Phone Book

Design a data structure to store your contacts: names of people along with their phone numbers. The data structure should be able to do the following quickly:

- Add and delete contacts,
- Lookup the phone number by name,
- Determine who is calling given their phone number.

- We need two Maps: (phone number → name) and (name → phone number)
- Implement these Maps as hash tables
- First, we will focus on the Map from phone numbers to names

#### Direct Addressing

- = int(123-45-67) = 1234567
- Create array Name of size 10<sup>L</sup> where L is the maximum allowed phone number length
- Store the name corresponding to phone number P in Name[int(P)]
- If no contact with phone number P, Name[int(P)] = N/A

#### Direct Addressing

Name

Natalie

N/A

N/A

. . .

Steve

N/A

. . .

Natalie: 123-45-67 → 1234567~

Steve: 223-23-23  $\rightarrow$  2232323-

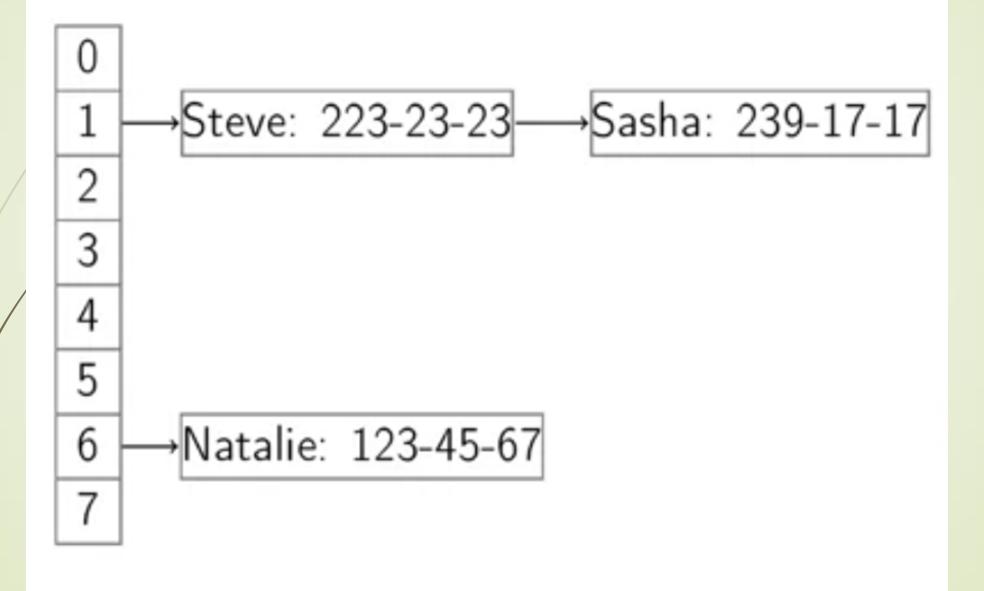

#### Direct Addressing

- Operations run in O(1)
- Memory usage:  $O(10^L)$ , where L is the maximum length of a phone number
- Problematic with international numbers of length 12 and more: we will need 10<sup>12</sup> bytes = 1TB to store one person's phone book — this won't fit in anyone's phone!

## Chaining

- Select hash function h with cardinality m
- Create array Name of size m
- Store chains in each cell of the array Name
- Chain Name[h(int(P))] contains the name for phone number P

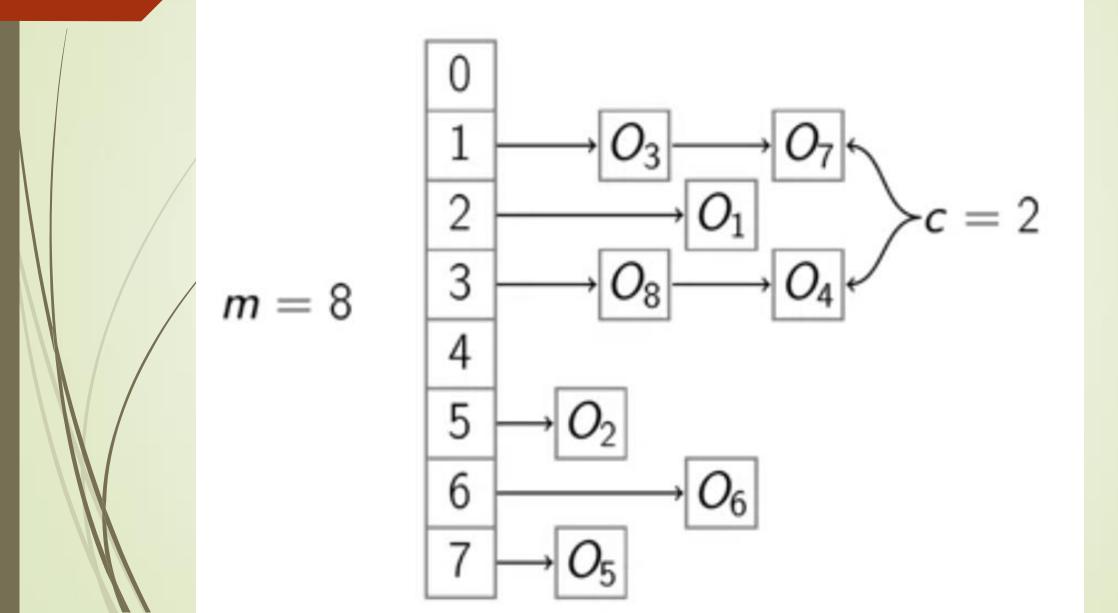

### Chaining

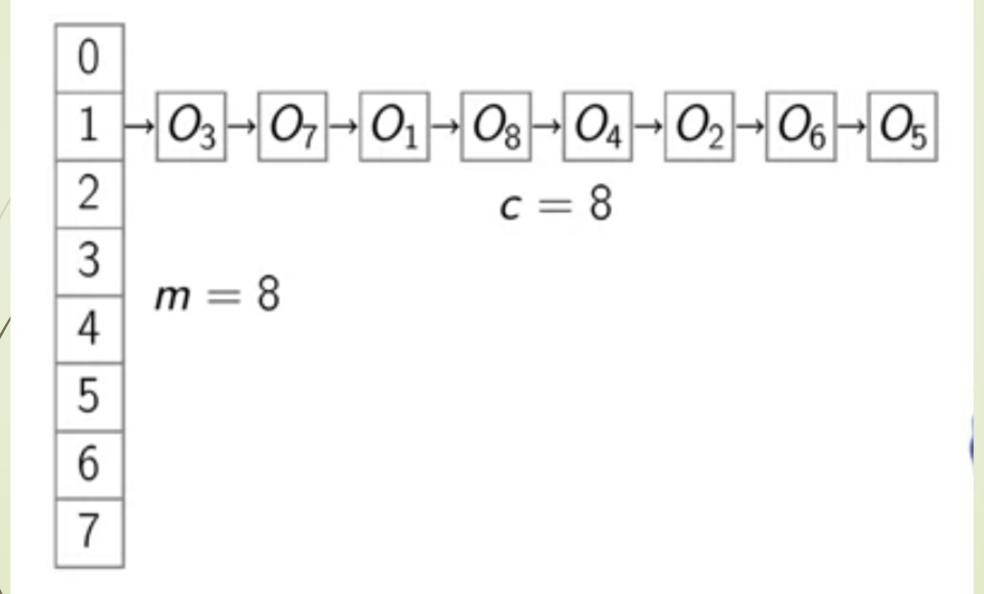

#### Parameters

- n phone numbers stored
- m cardinality of the hash function
- c length of the longest chain
- O(n+m) memory is used
- $\alpha = \frac{n}{m}$  is called load factor
- Operations run in time O(c+1)
- You want small m and c!

# Good Example

#### Bad Example

#### First Digits

- For the map from phone numbers to names, select m = 1000
- Hash function: take first three digits
- h(800-123-45-67) = 800
- Problem: area code h(425-234-55-67) = h(425-234-55-67)
- $h(425-234-55-67) = h(425-123-45-67) = h(425-223-23-23) = \cdots = 425$   $h(425-123-45-67) = h(425-223-23-23) = \cdots = 425$  $h(425-223-23-23) = \cdots = 425$

## Last Digits

- Select m = 1000
- Hash function: take last three digits
- h(800-123-45-67) = 567
- Problem if many phone numbers end with three zeros

#### Random Value

- Select *m* = 1000
- Hash function: random number between 0 and 999
- Uniform distribution of hash values
- Different value when hash function called again — we won't be able to find anything!
- Hash function must be deterministic

#### Good Hash Functions

- Deterministic
- Fast to compute
- Distributes keys well into different cells
- Few collisions

Thank,
